

Equalizer in optical receiver

Overview

In the optical domain, an equalizer is a device that equalizes the gain response over a particular wavelength range. The main reason for this equalization is to enable the cascading of amplifiers. Equalization is the process of applying a filter (the "equalizer") at the receiver to undo the distortions introduced by the channel. The goal is to restore the transmitted signal to its original shape as closely as possible. The Equalizer as an Inverse Filter: Ideally, the equalizer would be the. We perform a feasibility study of implementing a 16-QAM 112-Gbit/s decision directed equalizer on a state-of-the-art FPGA platform. For-the-first-time, it was integrated into a silicon transmitter, delivering doubled bandwidth (60 GHz) and >3 dB SNR enhancement at 66GBaud.
