

Experimental Principle of Optical Transmitter

Overview

The Mach-Zehnder modulator (MZM) is a device that uses the principle of interference between propagating signals to generate amplitude and phase modulation. Its name stems from the fact that the structure employed to generate it. The Mach-Zehnder modulator (MZM) is a device that uses the principle of interference between propagating signals to generate amplitude and phase modulation. Its name stems from the fact that the structure employed to generate interference between the propagating signals is based on a Mach-Zehnder interferometer (MZI), as illustrated in Fig. 2.12. In addition to conveying information in the phase and amplitude of the optical signal, digital coherent optical systems also use polarization as an additional degree of freedom. Single-mode optical fibers support two degenerate (having the same propagation constant) optical modes, with orthogonal polarization orientations.
