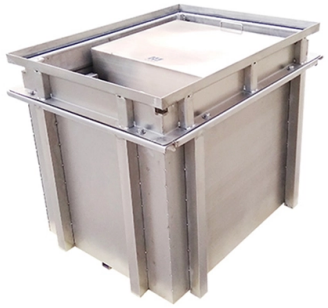
Transmission Interface Optical Module



Overview

An optical transceiver module, often simply called an optical module, acts as a signal conversion interface in fiber optic networks. It transforms high volumes of electrical signals into optical signals for transmission over fiber cables, or reverses the process at the receiving. An optical module is a typically hot-pluggable optical transceiver used in high-bandwidth data communications applications. Optical modules typically have an electrical interface on the side that connects to the inside of the system and an optical interface on the side that connects to the outside. Some functions can be configured on an optical interface only after the interface connects to a transmission medium (such as an optical module or copper module). Therefore, optical interfaces must connect to transmission media before configuration of these functions. Its primary function entails converting electrical signals into optical signals.
